1 Introduction

The rapid growth of digital media has significantly changed how people consume information, but it has also introduced a serious societal issue: the widespread dissemination of misinformation. With the rise of social media platforms, online news outlets, and user-generated content, individuals are exposed to vast amounts of information daily, much of which may be misleading, biased, or entirely false. According to studies by organizations such as the Pew Research Center, a large percentage of Americans regularly encounter misleading or inaccurate information online. This issue has far-reaching consequences, including the erosion of public trust, the spread of harmful narratives, and poor decision-making in areas such as health, politics, and finance.

Current solutions to misinformation often rely on manual fact-checking or user initiative, requiring individuals to verify content themselves. These approaches are inefficient, time-consuming, and often unrealistic given how quickly information is consumed. Additionally, many users lack the tools or expertise to critically evaluate the credibility of sources in real time. Therefore, there is a clear need for a system that can automatically help users identify potentially misleading content as they browse the internet without disrupting their experience.

To address this issue, this project introduces RedFlag, a browser extension and desktop application that automatically detects and flags potentially misleading or inaccurate content in real time. RedFlag runs in the background while users browse, analyzing content and providing contextual warnings when needed. Rather than requiring active user input, the system integrates seamlessly into the browsing experience, offering clear explanations and optional interaction with an AI-powered assistant. By combining automation, user control, and transparency, RedFlag aims to empower users to make more informed decisions and reduce the impact of misinformation in digital spaces. The product will be demonstrated through a prototype that highlights its core functionality, usability, and effectiveness in addressing this growing societal problem.

2 Product Description

RedFlag is a software solution designed to combat online misinformation by automatically analyzing digital content in real time and providing users with warnings when potentially misleading information is detected. The system is implemented as both a browser extension and a desktop application, allowing it to integrate seamlessly into a user's normal browsing experience. The primary goal of RedFlag is to enhance digital literacy and promote informed decision-making by giving users immediate insights into the credibility of the content they encounter.

The solution focuses on automation, transparency, and user control. RedFlag does not require users to manually submit content for analysis; instead, it continuously monitors web pages in the background. When questionable information is identified, the system generates a non-intrusive alert along with an explanation of why the content was flagged. Users can then choose to explore additional details, ignore the warning, or provide feedback to improve the system. Ultimately, RedFlag aims to reduce the spread and influence of misinformation while maintaining a smooth and customizable user experience.

2.1 Key Product Features and Capabilities

RedFlag offers several key features that set it apart from traditional fact-checking tools. First, it performs automatic, real-time content analysis, allowing users to receive feedback without interrupting their browsing workflow. This background operation ensures continuous support without requiring any additional steps.

Another significant feature is its contextual warning system, which alerts users when content may be misleading. These warnings include clear explanations of why the content was flagged, helping users understand the reasoning behind the system's analysis rather than simply presenting a binary judgment. This transparency builds trust and encourages critical thinking.

RedFlag also includes a user feedback mechanism that lets individuals report incorrect flags or confirm accurate ones. This feature helps improve the system over time by incorporating human input into the analysis. Additionally, users have customization options, such as enabling or disabling the extension on specific websites and choosing when to expand or ignore warnings.

Finally, integrating an AI-powered chat assistant enables users to engage more deeply with the system. The assistant can explain flagged content in greater detail and guide users in independently identifying misinformation. Together, these features make RedFlag a comprehensive and innovative solution for addressing misinformation in real time.

2.2 Major Components (Hardware/Software)

RedFlag primarily relies on software components, with minimal hardware requirements beyond a standard personal computer or laptop capable of running modern web browsers. The system is designed to run on widely used platforms, including Google Chrome and desktop operating systems such as Windows and macOS. No specialized hardware is required, making the solution accessible to a broad range of users.

The software architecture consists of several major components. The browser extension serves as the front-end interface, interacting directly with web pages and displaying warnings to users. A background processing module handles real-time content analysis, leveraging natural language processing and machine learning techniques to evaluate the credibility of information.

A backend server supports the system by managing data, storing flagged content, and processing user feedback. This backend may also integrate external APIs for fact-checking or credibility scoring. Additionally, the AI chat assistant component provides an interactive interface for users seeking deeper explanations.

These components are structured in a modular architecture, allowing for scalability and future enhancements. The separation of front-end, backend, and analysis modules ensures that RedFlag remains efficient, maintainable, and adaptable as new technologies and data sources are incorporated.

3 Identification of Case Study

- For whom is this product being developed? Why?
- Identify case study group—the small group of users who will use app prototype and provide feedback.
- Who else might use this in the future?

4 Glossary

Misinformation: False or misleading information that is spread regardless of intent to deceive.

Browser Extension: A software module that adds specific functionality to a web browser.

Natural Language Processing (NLP): A field of artificial intelligence that focuses on the interaction between computers and human language.

AI Assistant: A software agent that uses artificial intelligence to provide interactive assistance and explanations to users.

Backend Server: A system that processes data, manages application logic, and supports front-end operations.

Real-Time Analysis: The ability to process and evaluate data instantly as it is received.
